

Title

Intensive nurse-administered disease management versus routine care in inflammatory bowel disease: randomized trial of patient-centered outcomes

Abstract

Specialist nursing coordination plays a vital role in IBD management, yet rigorous evidence on intensive nurse-led models remains limited. This randomized trial compared two care approaches in 98 patients with IBD newly commencing advanced immunosuppressive therapies. Participants were randomly assigned (intensive arm n=50, control arm n=48) to either weekly nurse contact including scheduled telephone check-ins and in-person clinic visits, or standard care involving baseline education only. The primary outcome was change in an integrated disease-burden assessment score at 12 weeks. Both groups showed improvement in disease-burden measures; however, the intensive-contact arm demonstrated significantly greater score reductions. At 12 weeks, substantially more intensive-contact participants achieved clinically meaningful treatment response. By 52-week follow-up, the intensive-contact group maintained superior disease-control trajectories and higher rates of disease remission. Adverse event profiles were comparable between arms. Results support intensive nurse-led management for improving disease trajectories and outcomes in patients initiating advanced IBD therapies.
