

Title

Personalized Psychological Intervention for Fibromyalgia: Randomized Protocol for Assessing Cognitive-Behavioral Therapy as an Adjunct to Routine Care

Abstract

Fibromyalgia syndrome represents a common chronic pain disorder with associated psychological comorbidities including anxiety, depression, and sleep disruption. Cognitive-behavioral interventions show promise in fibromyalgia management, yet evidence for individualized programs delivered alongside standard medical care remains limited. This protocol describes a single-blinded randomized trial enrolling 70 participants meeting diagnostic criteria at a tertiary rehabilitation center. The intervention arm will receive 10 weeks of therapist-administered individualized cognitive-behavioral programming tailored to each participant's specific symptom profile and psychosocial stressors, delivered concurrently with ongoing routine pharmacologic and rehabilitative treatment. Control participants continue standard care alone. Outcome domains encompass validated measures of anxiety, depression, sleep architecture, emotional processing, and disease-specific functional capacity. This study will clarify whether personalized psychological intervention augments treatment response in this population.
