

Title

Twenty-Four-Hour Intraocular Pressure Response to Sepetaprost Compared With Latanoprost in Glaucoma Patients

Abstract

Sepetaprost represents a novel prostaglandin formulation with potential therapeutic benefits for glaucoma management. In this exploratory trial, 33 adults with glaucoma or ocular hypertension received either sepetaprost (n=17) or latanoprost (n=16) daily for 12 weeks. At the end of treatment, mean 24-hour intraocular pressure was numerically lower in the sepetaprost group relative to latanoprost, though this difference did not achieve statistical significance at the pre-specified threshold. Nocturnal intraocular pressure measurements demonstrated a trend toward lower values with sepetaprost. Both agents reduced intraocular pressure from baseline by approximately 5-7 mmHg. Adverse events were frequent in both groups, occurring in the majority of participants. Safety profiles were comparable between the two treatments. These findings suggest sepetaprost warrants further investigation in adequately powered studies to clarify its role in glaucoma management.
