

Title

Efficacy and Safety of Oral Ziltravir in Early COVID-19: Protocol for a Phase 3, Randomized, Placebo-Controlled Trial

Abstract

Background: Accessible oral antiviral treatments remain critical for preventing COVID-19 progression. This protocol describes a trial evaluating ziltravir, a novel oral RNA-dependent RNA polymerase inhibitor, in non-hospitalized adults. **Methods:**

This is a phase 3, multicenter, double-blind, placebo-controlled trial.

Approximately 1,050 symptomatic adults with mild-to-moderate COVID-19 and at least one risk factor for severe disease will be randomized 1:1 to receive ziltravir (800 mg twice daily) or a matching placebo for 5 days. The primary endpoint is the incidence of COVID-19-related hospitalization or all-cause mortality by day 28. Secondary endpoints include time to sustained symptom resolution, viral load reduction, and safety metrics. **Discussion:** This trial will determine whether early intervention with ziltravir safely and effectively mitigates severe COVID-19 outcomes in high-risk outpatients, potentially offering a new therapeutic option for clinical management.
